

GRAPHICS IN BUSINESS

PAUL COOPER
SYSTEMS ENGINEER
TULSA, OKLAHOMA

Although there is no graphics software language currently supported on the HP3000, many products are offered to give the 3000 user excellent business graphics capability. One of these products, the HP2648A, especially lends itself to business graphics because of the terminal oriented nature of the HP3000.

My purpose here is to explore some ways of applying graphics to business applications. In the past, graphics have been primarily used in scientific and engineering applications because graphics technology was developed for those kinds of jobs. The business data processing area is on the brink of a new era in data reporting through the use of graphics.

Looking at the users of information output from business systems, a hierarchy of job positions can be seen as shown in the following chart:

MANAGEMENT REPORTING

STAIRSTEPS

This hierarchy will be referred to throughout this presentation as possibilities for graphics applications are explored.

Of prime consideration for a planner/expeditor type person is "How is the output of my department doing with respect to schedule?". In the past, reports have been available to show at any given instant, what the schedule number of output units are versus actual output. Typically, there have been time lags between reported data and actual output data. These time lags make scheduling very difficult. In addition, data of this type ignores the time continuum needed to know where one stands with respect to remaining schedule and time.

With a simple graph, one can easily tell at a glance not only where one stands today but also over a time continuum. The fact that the output is coming from a terminal oriented system allows the user the ability of reporting this information on a "pseudo-real-time" basis, thus eliminating the confusing time lags between reported and actual.

Figure 1 would be a good example of a planner's tool from a batch type system. The planner should expect to get this type of information the day after the output actually takes place. The list would point out that 181 units were output as of the end of M-Day 13, but it

would not indicate how the production line is doing so far during the current day.

It may also be a good example of a planner's tool from an online system. In this case, the information would be much more timely and therefore much more useable. The information should be expected to be available at any hour of any M-Day, and should be expected to reflect output already finished during the current day.

Graph 1 shows this same planner's tool graphically. Note that not only does the graph indicate production to date, but also gives an excellent trend line to let the planner know what needs to be done between now and the end of the production period. It answers questions like, "Do I need to recommend overtime to management", or "Do I have a problem with material flow?".

Notice also, that during the current day an indication is given as to whether the ahead/behind trend is being impacted by the current day's production. This indication is given by the slope of the graph line during the current day.

While this type of detail information is important to the planner, the first level supervision may well be more interested in more long-term type information. Again the same progression of data reporting can be seen at this level. Figure 2 is an example of year to date type information. The same kind of "timely information" parameters

apply to this reporting level.

In addition, some modelling is in order at this level to indicate to management what the year end production will be if projected at current production levels. There are a number of good forecasting methods which may be used to extend the production line out through the end of the year or beyond. This kind of information is essential for good manpower planning and for good material control.

Another topic of great importance to first line supervision and also to department managers is that of productivity. One measure of productivity is "dollars per manhour". The method I've chosen to work with here is number of dollars transferred from a production department versus the amount of labor applied. Going back to our earlier example, I've applied an arbitrary price to the units in the graph. In addition, I've established an arbitrary standard time for producing one of the units. This new data is represented in chart form in figure 3. Although this is a very simplified example of productivity measurement, the following conclusion can easily be reached: Data of this type can be understood much more simply and easily when it is presented graphically. Again, the graph which results from this data shows a trend over a time continuum. This trend cannot be readily gleaned from the same data presented in the traditional columnar form.

Efficiency is another topic of importance to management at this level. Efficiency is derived by comparing actual time spent on a unit to a predetermined standard time. Efficiency is usually shown as a percentage, which is easily understood as a number and does not need to be depicted graphically. But managing efficiency cannot be accomplished by a snapshot of any one particular time period. Here again, a group of percentages spread over time is needed to spot trends. With a computer, the current day's efficiency can be reported with respect to past days, and probably more important, a moving average can be derived and displayed quickly. This kind of information is very useful for spotting trends in efficiency to enable management to be responsive to developing problems. Figure 4 shows data of this type.

Middle and top level management are interested in more long-term information. Managers at this level are interested in topics like "What are my projected sales over the next 24 months?" or "How is my business doing compared to others in this industry?". Using forecasting algorithms, the computer can easily be made to project future trends based upon past performance and expected future trends in the market place. Adding graphics to these projections produces a pictorial view of future trends, making the data very easy to understand. The

whole idea of making projections (modelling) is to enable management to set a direction for future business. Questions about manpower, material, and financial requirements can be answered in this manner. It is incumbent upon data processing systems to report this information in any easy to understand and readily useable form. Graphics capabilities make this requirement easy to fulfill.

Figure 5 is an example of forecasted sales in the form one might expect to see from conventional systems. The corresponding graph makes the data much more digestible and easier to comprehend at a glance.

Figure 6 is an example of trend analysis. This type of data answers the question about how my business is doing with respect to the rest of the industry. Industry data is available from Dunn and Bradstreet or the Securities and Exchange Commission. A manager can place his company in perspective over time to see how the company is performing and whether the performance is improving or degrading over time.

To this point we've looked at reporting to all five levels of management through the use of linear graphs. A short mention should be given to the ease of generating these graphs on an HP2648. The fact is that the HP2648 has an autoplot function imbedded in firmware within

the terminal. The autoplot function is complete with a menu to describe the X and Y axes. Once the axes are described, the terminal will draw the graph, with tic marks and an optional grid. Data for the graph can be obtained either from the display or from the HP3000. With this versatility, linear graphs become very easy to generate.

The next area of importance to business graphics is generating other types of general purpose report forms. One example of this type of report is a pie chart. Unlike linear graphs, there is no firmware driven menu to generate a pie chart. However, with a little imagination, a simple program can be written to accomplish this feat. Appendix 1 to this report is a source listing of a Fortran program which generates a pie chart. Going through the program, one can see that the terminal graphics are controlled through the use of "escape sequences". The sequences are easily edited into a source program or data file through the use of the editor. This program is included here to demonstrate the relative ease of generating business graphics, and is intended to stimulate the imagination.

Over the past few years, the data processing industry has seen a migration of trends. From batch systems to interactive systems; from main frame processing

to distributed processing. The industry has also seen a shift in the way people think about computers. The computer is losing its' shroud of mystery and is becoming a tool to aid businessmen accomplish goals and plan for the future. Data reporting through graphics is a natural extension to these trends and opens a whole new methodology for data reporting.
