

SOFTWARE QUALITY CONTROL

C. EDWARD McVANEY
J. D. EDWARDS & COMPANY

The Predicament

Computers have brought space age technology to the ordinary businessman. Their potential seems boundless; the electronic equipment (hardware) is usually superlative; but the computer programs (software) can bring a plague to your organization.

The hardware side of the computer industry seems to be far more advanced than its software counterpart. The gripes and groans about computer failures are not all without substance, and ninety-nine times out of a hundred it seems it is the software that is at fault.

You have to have software! The computer won't work without it! But what do you do? How do you protect yourself? How do you assure a high quality result?

Knowing what to look for, and how to judge quality software, need not be a great mystery. You don't have to be a computer technician to make meaningful value judgments. Your common sense will serve you well if you're willing to do some research.

Before we go much further, we should make a clear distinction between "systems" and "applications" software. Applications software is the term computer specialists use to identify major business systems on a computer. For example:

- . Payroll Systems
- . Inventory Systems
- . Billing Systems, and
- . Accounting Systems

Applications software is sometimes referred to as a software system, a software package or just a system. In addition to the individual computer programs (usually ranging from 10 to 100 programs), it would include all the supporting documentation and related professional services including training and on-going maintenance.

Systems software, on the other hand, is a term used to describe the family of computer programs that are used by the computer to do its own work. For example:

- . Operating System
- . Compilers
- . Utility Programs, and
- . Communication Monitors

2. Systems Documentation - Documentation is to a computer system what a shop manual is to a mechanic - it is not very important until you need it. Systems documentation should consist of:

- . Samples of Each Report
- . Illustrations of each Video Display
- . Copies of Forms and Documents
- . A Glossary of Terms and Codes
- . Clerical Procedures
- . Computer Operating Instructions
- . Program Descriptions
- . Data Base Descriptions, and
- . Other Appropriate Material

If these items are not readily available and professionally packaged so that they are easy to understand, you've noted a serious weakness in the system. You will be vulnerable to turnover of personnel and empire building if you don't have good documentation.

3. Clerical Procedures - Computer specialists have been known to forget about the people who have to use the system. Check the clerical operating procedures including the video terminal operating instructions to see if they are simple and effective. There's no need to explain the mundane, but at the very least, the unusual aspects of the system should be explained.

Of course, checking for voids goes beyond the particulars we've noted here - video displays, operating reports, input journals, forms, data bank, accounting controls and so on.

(b) Fitness to Your Needs

In their eagerness to sell computer hardware, salesmen have been known to recommend a software system that didn't quite fit. Major misfits are not uncommon.

If you are told that your organization can be changed or adapted to fit the software, make sure you know what will have to be changed. A good software package should provide definable improvements to the flow of work within your business with a minimum of organizational or procedural changes. It had better, because modification costs dearly, not only in terms of time and money but, more importantly, because vital management data often will not be available while the modification is being done. The "data gap" can be filled, of course, by keeping a manual or semi-automated system running parallel with the computer, but we can't imagine any business owner wanting to do that for very long.

(c) Maintenance Costs

Good software packages, like good automobiles, don't require much maintenance. If a computer programmer has to devote a significant part of his time to maintaining a software system, you can bet it is poorly designed or poorly programmed. Conversely, if little or no maintenance is required, you should be encouraged.

The maintenance cost of an acquired software package can often be determined by consulting with other users whose names the vendor has given you as references.

(d) Feature Comparisons

Another effective technique for judging software quality is feature comparisons between comparable systems. This is basic consumerism. These features include:

- . Processing Capacity
- . Hardware Requirements
- . Management Accounting Techniques
- . Data Base Concepts
- . Timeliness of Reports
- . Video Screen Features
- . Audit Controls, and
- . Others, as appropriate

Many of the little "extras" in a software system are well worth having.

(e) Operating Costs

If a software package does not reduce operating costs (clerical salaries, etc.) or provide significant intangible benefits such as improved management information or better customer service, then something is wrong.

Innumerable software systems have been installed with the anticipation of reduced operating cost and significant intangible benefits only to have just the opposite come true.

Therefore, you should check the "track record" or references of a software system to see if it has performed as promised. While you're checking references, ask about programmer maintenance costs.

(f) Real Response

Video terminal computer systems should provide for almost instantaneous entry of data, updating of records and redisplay of updated records. Many software packages fall far short of this capability. It is not uncommon to find video terminal packages that do nothing more than conventional "key-punching" into the video terminals and then process the data in the off hours. If this is the case, computer records might not be updated until the next morning even though video terminals were used for data entry.

(g) Technical Support

Behind every good computer system there should be good people to provide the technical support that, from time to time, you may need to rely on.

Do these people know and understand your business? Are they competent enough to get things done? What is their track record? Where will they be a year from now when you need them? Is this a one man show or a professional team of computer specialists? You should answer these questions and assure yourself of proper support.

Technical support personnel are all important to the success of your system.

(h) Conventional Technology

More often than you might expect, computer systems are developed using non-standard technology, i.e. offbeat programming languages, homemade systems software, and mix 'n' match equipment. Beware of these approaches because they invariably create inflexibility, overdependence on support personnel, and early obsolescence.

(i) Data Controls

Precise control features are essential to the success of any software package. Check to see that edit controls are installed to check the accuracy, reasonableness and inter-relationship of all input transactions. Also check to see that input balancing controls are in effect. The system should have provision for a complete audit trail of all sensitive transactions. This audit trail should balance to master file control totals and reference back to the originating entries.

(j) Predefined Standards

A very effective way to evaluate the quality of a software system is to compare it to independent standards of excellence.

J. D. Edwards & Company has developed such standards, establishing criteria for, among other items:

- . Systems Documentation
- . Input Controls
- . Accounting Controls
- . Data Base Design
- . Computer Processing
- . Report Design
- . Programming Structure
- . Programming Efficiency, and
- . Numerous other items.

Some Classic Examples

We have said that you don't have to be a computer expert to judge the quality of a software package. Let's illustrate how you may judge software quality with simple examples of a computer report and an input document.

(a) Report Quality

Illustration Number 1 represents a construction loan status report for Mr. Charles Louis who is building a new home. This report is a classic example of computerized goobledygook. Note the following deficiencies which could be readily detected by a non-technician.

1. The name and address were typed rather than printed by the computer.
2. The following columnar headings are unintelligible:

. BR	. TY
. WM	. MB
. TEL	. OV
. TY	. TY DB
. CD	
3. Note that there are three columns labeled TY.
4. Even if you understood what the codes mean, how would you understand the data? What, for example, does "I" mean in the MB column?

Mr. Charles Louis was somewhat perplexed. He felt insecure because he didn't understand what the report said. So he took the report to his CPA and asked him to explain it - he was equally baffled.

(b) Input Forms Quality

1. What do the arrows mean?
2. What are:
 - . OIT#
 - . NC
 - . J#
 - . RES Code
 - . Fld Code?
3. What do you enter in the four digit date field?

The point is that neither computer input nor output forms need be as complex as many computer people make them. Look at Illustration Number 3, for example, the "Account Master Revisions" form reproduced on the next page. All column headings are in plain English - not computerese. Codes are plainly defined at the bottom of the sheet. There is plenty of room to write, and there are no mysterious arrows or slash marks.

The "Labor Cost Analysis," Illustration Number 4, shows that computer output needn't be gobbledygook either. This weekly report on a construction project can be easily read by a non-expert. It keeps jargon and confusing abbreviations to a minimum.

The Make versus Buy Decision

In theory, buying a software package should offer the advantages of having:

- . Lower start-up costs, and
- . Shorter start-up intervals.

In practice, things don't often work out that way. Many experienced data processors are skeptical of these supposed advantages - particularly when modification or changes to the software packages are required. Indeed, the more accomplished computer user often steers clear of purchased software packages all together.

On the other hand, custom designed and programmed software supposedly offers the advantages of being:

- . Better suited to your operation needs,
- . More flexible,
- . Easier to maintain, and
- . Less expensive to operate.

But custom designed and programmed software systems are not without peril. If you don't have access to a highly qualified team of systems analysts and computer programmers (either as in-house employees or outside contractors), you shouldn't try to develop a custom system.

A well designed custom system is, in the long run, usually more effective than a purchased system. If your needs are unique in any way, and you can afford to do it right the first time, you should seriously consider custom designed and programmed software packages. After all, you've probably custom fit every other aspect of your business, so why not do the same with you computer software.

What It Should Cost

If software were cheap, the big, experienced users of computers would have known it long ago. Experienced computer users may invest nearly as much (sometimes even more) in software as hardware.

It would be nice if one or two thousand dollars of software were all you needed, but unless your business fits an available ready-made package very closely, you should plan on spending anywhere from 40% to 100% of the computer purchase price on software, depending on your needs.

Once More From The Beginning

When it's all said and done, what you really want is:

- . Better Management Information
- . Reduced Operating Costs
- . More Flexible Business Systems, and a
- . Decent Return on Your Investment.

Today's computers have the potential to do all of that in a most pleasing way - but be careful!

Software - particularly applications software - can be the fly in the ointment.

- . Check out each component of the system
- . Use common sense and be critical
- . Ask for professional help in technical areas
- . Follow a sound evaluation methodology
- . Look for voids, fitness for your needs, maintenance headaches, effective features and operating economics.
- . Be very careful about technical support personnel, and
- . Use predefined standards or evaluation criteria if you have access to them.

Finally, don't be tempted by low-cost or no-cost software purely because of price - or rule out a custom-design purely because of high start-up cost. But you're not likely to do either if you've been thorough up to the point of cost considerations. Remember that old saying

The bitterness of poor quality remains long after the sweetness of low price is forgotten.
